Rate of evapotranspiration		Climate Resilience Water Management
<b>Description and justification</b>	Evapotranspiration (ET) is a combination of two separate processes whereby water is lost from the soil surface by evaporation and from vegetation by transpiration. Water evaporates from surfaces when sufficient heat is supplied for liquid water to transition to water vapour. During transpiration, plant tissues vaporise water, which is then released to the atmosphere through stomatal openings on	

	<p>the plant leaf. Nearly all water taken up by plants is released to the atmosphere through transpiration. In addition to the non-uniformity of urban vegetation, shading of urban vegetation by landscape trees and structures and edge effects due to the relatively small scale of urban green space in comparison to commercial crop fields can significantly influence <math>ET</math> (Snyder, Pedras, Montazar, Henry, &amp; Ackley, 2015).</p>
<b>Definition</b>	<p>Measured or modelled evapotranspiration (typically expressed in mm per unit time)</p>
<b>Strengths and weaknesses</b>	<ul style="list-style-type: none"> <li>+ The reference evapotranspiration, <math>ET_o</math>, provides a standard to which: (a) evapotranspiration at different periods of the year or in other regions can be compared; (b) evapotranspiration of other crops can be related (Allen, Pereira, Raes, &amp; Smith, 1998).</li> <li>+ Standard, widely-applied technique</li> <li>- Challenging and expensive to measure directly</li> <li>- Requires high level of expertise to apply</li> </ul>
<b>Measurement procedure and tool</b>	<p>Evapotranspiration is measured involving specific devices and accurate measurements of various physical parameters or the soil water balance in lysimeters.</p> <p>In practice, <math>ET</math> is commonly calculated using meteorological data. Commercially-available <math>ET</math> monitoring stations are generally meteorological stations that calculate potential <math>ET</math> using monitored temperature, relative humidity, wind speed and direction, solar radiation, and precipitation data. The Penman-Monteith equation is the FAO-recommended standard technique for calculation of reference evapotranspiration, <math>ET_o</math> from crops (Allen, Pereira, Raes, &amp; Smith, 1998). The FAO Penman-Monteith method to estimate <math>ET_o</math> is presented in Equation 1:</p> $ET_o = \frac{0.408\Delta(R_n - G) + \gamma \frac{900}{T + 273} u_2 (e_s - e_a)}{\Delta + \gamma(1 + 0.34u_2)} \quad (1)$ <p>Where <math>ET_o</math> is reference evapotranspiration [<math>\text{mm day}^{-1}</math>], <math>R_n</math> is net radiation at the crop surface [<math>\text{MJ m}^{-2} \text{day}^{-1}</math>], <math>G</math> is soil heat flux density [<math>\text{MJ m}^{-2} \text{day}^{-1}</math>], <math>T</math> is mean daily air temperature at 2 m height [<math>^{\circ}\text{C}</math>], <math>u_2</math> is wind speed at 2 m height [<math>\text{m s}^{-1}</math>], <math>e_s</math> is saturation vapour pressure [<math>\text{kPa}</math>], <math>e_a</math> is actual vapour pressure [<math>\text{kPa}</math>], <math>e_s - e_a</math> is saturation vapour pressure deficit [<math>\text{kPa}</math>], <math>D</math> is slope vapour pressure curve [<math>\text{kPa } ^{\circ}\text{C}^{-1}</math>], and <math>g</math> is psychrometric constant [<math>\text{kPa } ^{\circ}\text{C}^{-1}</math>].</p> <p>Using the Penman-Monteith equation, <math>ET</math> from plant surfaces under standard conditions is determined using an experimentally-determined coefficient (<math>k_c</math>) to relate the <math>ET</math> for</p>

	<p>a specific crop species, <math>ET_c</math>, to <math>ET_0</math>. Thus, for a given crop species:</p> $ET_c = k_c \times ET_0 \quad (2)$ <p>For urban landscapes, the landscape coefficient method (LCM), which uses a different set of coefficients rather than <math>k_c</math> to estimate ET, may be more appropriate (Costello, Matheny, Clark, &amp; Jones, 2000):</p> $ET = k_L \times ET = k_d \times k_s \times k_{mc} \times ET_0 \quad (3)$ <p>where <math>k_L</math> is a landscape coefficient defined as a product of <math>k_d</math>, a planting density factor, <math>k_s</math>, a species-specific factor, and <math>k_{mc}</math>, a microclimate factor.</p> <p>The modifications of the Penman-Monteith equation for plant-specific conditions can be found in the publications by, e.g., Litvak and Pataki (2016) and Litvak, Manago, Hogue, and Pataki (2016).</p>
<b>Scale of measurement</b>	Plot scale, can be extrapolated using land cover data
<b>Data source</b>	
<b>Required data</b>	Radiation, air temperature, wind speed, vapour pressure, soil heat flux density
<b>Data input type</b>	Quantitative
<b>Data collection frequency</b>	Annually, and before and after NBS implementation
<b>Level of expertise required</b>	High – requires the ability to apply the Penman-Monteith equation and evaluate the results
<b>Synergies with other indicators</b>	Related to <i>Daily temperature range</i> , <i>Land surface temperature</i> and <i>Surface reflectance - Albedo</i> indicators; a possible consequence of <i>Green space management</i> and <i>Urban regeneration</i> indicator groups
<b>Connection with SDGs</b>	SDG 11 Sustainable cities and communities
<b>Opportunities for participatory data collection</b>	No opportunities identified
<b>Additional information</b>

Peak Flow Variation	Water Management
<b>Description and justification</b>	<p>The peakflow is the maximum value of the flowrate due to a given rain event. It indicates how much the discharge in a river or a stormwater network is impacted by the use of NBS.</p> <p>It can be used to :</p> <ul style="list-style-type: none"> <li>• assess one NBS type benefit</li> <li>• assess the impact of a combination of NBS set on one large catchment</li> </ul>
<b>Definition</b>	<p>Peakflow variation is defined by the relative error in peakflow between the peakflow of the catchment with NBS and the peakflow of a catchment without NBS (% (but flowrates are in l/s or l/s/ha (in case of different catchments comparison))).</p>
<b>Strengths and weaknesses</b>	<p>This indicator will directly assess the impact of NBS in the reduction of the flowrate, which peakflow is a characteristic value.</p>
