

Square lake representation at the Brague catchment scale on flood disaster of Oct. 2005: the full FEV of 1.9 Mm<sup>3</sup> is equivalent to a square lake of side nearly 1 km long and 2 m deep. The existing retention concrete basin of 10,700 m3 handle less than 1% of this total volume at high cost. Giving 30 m of width to the river would cope with 42% of the FEV while the natural retention areas would cope with 26% of the FEV at low cost. 31% of FEV remains and require other measures if one want to protect against the full event.z

## 4.20 Rainfall interception rate of NBS

Project Name: OPERANDUM (Grant Agreement no. 776848)

**Author/s and affiliations:** Slobodan B. Mickovski<sup>1</sup>, Alejandro Gonzalez-Ollauri<sup>1</sup>, Karen Munro<sup>1</sup>

| Rainfall interception rate of NBS |   | Water Management              |
|-----------------------------------|---|-------------------------------|
| Description and justification     | The aerial parts of vegetation established as part of the NBS can intercept precipitation and thus decrease and delay the amount of water reaching the soil which, in turn, will decrease the risk of erosion and landslides. |                               |
| Definition                        | Interception rate refers to the that does not reach the soil, I the leaves, branches of plants  | but is instead intercepted by |

| Strengths and<br>weaknesses+ Well established procedures exist for NBS that include<br>trees; large body of empirical models exist for multiple<br>plant species and biomes.<br>- Requires significant effort and suitably qualified<br>workforce for measurement/monitoring; relatively difficult<br>to measure under non-woody vegetation; it is difficult to<br>capture the complex architecture of the canopy; high<br>interference with dripfall and atmospheric turbulence.Measurement<br>procedure and<br>toolThe rationale for measurement is to measure rainfall<br>below the canopy and beyond the canopy; influence and<br>compare both through linear regression, subtract<br>throughfall and stemflow quantities from it. These<br>quantities can be measured using a rain gauge/graded<br>containerScale of<br>measurementPoint (tree or individual vegetation), field (meso scale)Data sourceRequired dataRequired dataWater volume; canopy crown area; canopy cover fraction:<br>leaf area indexData collection<br>frequencyDuring every rainfall eventLevel of expertise<br>requiredMoisture content, stemflow, throughflow, vegetation type,<br>vegetation cover, precipitationConnection with<br>SDGs11,13,1,5,17Opportunities for<br>participatory data<br>collectionYesAdditional informationGonzalez-Ollauri, A. & Mickovski, S.B.
